A fault-tolerant design enables a system to continue its intended operation, possibly at a reduced level, rather than failing completely, when some part of the system fails. The term is most commonly used to describe computer systems designed to continue more or less fully operational with, perhaps, a reduction in throughput or an increase in response time in the event of some partial failure.

Fault tolerance refers to the ability of a system (computer, network, cloud cluster, etc.) to continue operating without interruption when one or more of its components fail. The objective of creating a fault-tolerant system is to prevent disruptions arising from a single point of failure, ensuring the high availability and business continuity of mission-critical applications or systems.

Fault Tolerant Strategies Fault tolerance in computer system is achieved through redundancy in hardware, software, information, and/or time. Such redundancy can be implemented in static, dynamic, or hybrid configurations. Fault tolerance can be achieved by the following techniques: Fault masking is any process that prevents faults in a system

This fault tolerant design typically includes hardware, software, power backup, and network fail-safe measures. Fault tolerance is a design that ensures a computer application will remain functioning in the event of catastrophic failure. Most banks, governments, and utility companies use this type design for their critical applications.
